Tufts Global Health CEA Registry (\$DALY)

Tufts CEA Registry (\$/QALY)

*Only partial data from 2019 is currently available. Full 2019 dataset is expected Fall 2020.

Growth of \$/DALY vs. \$/QALY Studies in LMICs

*Expected number of 2019 articles are based on an average of the prior 3 years (2016-2018)

Do Pandemic Response/Preparedness Studies Mirror These Trends?

- QALY-based studies assessing disease control/prevention: 38 (0.5%)
 - Over two-thirds were not policy-based (e.g., single drug or vaccine)
 - Studies of testing, stockpiling, suppression minimal
 - Highly variable results (range: \$440 to \$15m per QALY)
- DALY-based studies: 11 (1.6%)
 - 7/11 were policy-based
 - Systematic outbreak control, risk mitigation/prevention, etc.
 - Most highly cost-effective (<1x GDP), but...
 - Most missing implementation/monitoring costs

Thoughts on CEA in COVID-19 Context

- Gaps in clinical and public health preparedness play out daily
- No different for use of CEA to inform mitigation/control
- Clear need for further research
- Opportunity to build on disease modeling approaches to explore tradeoffs within local contexts given variability in estimates
 - E.g., for ~15,000 ventilators required for US today (95% UI: ~5,000 – ~40,000)*
